GUIs and CLIs are extraordinarily similar in what they do, but differ quite drastically in how they are used. The primary function of both GUIs and CLIs is to provide inputs to a computer to execute certain tasks. CLIs, in particular, are text-based interfaces that require specific lines of text to be entered to execute corresponding tasks. GUIs, on the other hand, utilize graphical icons to perform predetermined tasks. A common example of this would be an application icon on a homescreen. When the icon is pressed, an action is initiated and a specific task, opening the program, is completed. GUIs are notably easier to understand than CLIs. With CLIs, there are a plethora of lines of enterable text that each do a variety of different things. This creates a steep learning curve for anyone trying to operate a CLI. GUIs are comparatively way easier to operate, and as such, have become the industry standard for most operating systems. GUIs aren't perfect, though, and lack efficiency compared to CLIs. CLIs do not need any graphical rendering to execute their tasks, and they allow for very precise command execution. They are also easier to use when doing repetitive tasks.
